ABSTRACT

The National Marine Fisheries Service in cooperation with the Bonneville Power Administration is conducting a 6-year study of the effects of instream river flow on the passage time, survival, and migrational behavior of juvenile fall and summer (0-age) chinook salmon in John Day Reservoir. In 1983, the final year of juvenile sampling in the reservoir, research activities continued to refine flow/travel time relationships and distributional behavior of 0-age chinook salmon.

Fifteen groups (72,559 fish) of marked 0-age chinook salmon were wire-tagged, branded, and released into the tailrace at McNary Dam, and thirty-two groups (22,206 fish) were branded and released into the reservoir at various other sites.

Sampling at John Day Dam, utilizing the airlift pump system in the B and C slots of Turbine Intake Unit 3, captured 82,698 subyearling chinook salmon including 640 mark recoveries. Additional marks (458) were recovered from purse seine samples taken at various sites throughout the reservoir.

Weekly mean fork lengths of 0-age chinook salmon captured at McNary and John Day Dams and in the reservoir by purse seine ranged from 103 mm in mid-June to 166 mm in mid-December. Fish captured at the John Day Dam monitoring facility and by purse seine throughout the reservoir were in excellent condition. Preliminary analysis of stomach samples taken in 1982 and 1983 from purse seine catches indicates active feeding is taking place in the reservoir.

The average passage time of the fastest moving marked 0-age chinook salmon from McNary Dam to John Day Dam was 11 days (based on 25th percentile of mark recaptures). The average reservoir residence time (calculated from the median date of the mark recoveries from each group at John Day Dam) was 22 days.

Regression analysis was used to develop a description of the relationship of river flow to the rate of downstream movement of 0-age chinook salmon in John Day Keservoir in 1983. The slope of this line and the correlation coefficient (R) were not significantly different from zero.

INTRODUCTION

The National Marine Fisheries Service (NMFS), in cooperation with the Bonneville Power Administration (BPA), is conducting a 6-year study of the effects of flow on the migratory behavior and survival of juvenile fall and summer chinook salmon in John Day Reservoir (Lake Umatilla).

The objectives of the study are to:

1. Define the effect of instream flow on the passage time and rate of downstream movement of 0-age chinook salmon in John Day Reservoir.
2. Define the effect of instream flow levels on the distribution and passage behavior of 0-age chinook salmon in John Day Reservoir.
3. Define the effect of reservoir passage time on relative survival of 0-age chinook salmon.

The study is divided into 3 years (1981-83) of juvenile marking and recovery of marks to define flow/travel time relationships and 3 years (1984-86) of recoveries of marked adults to define flow/survival relationships. This report summarizes results of research activities conducted during the final year of juvenile marking and recovery.

METHODS

Groups of 0-age chinook salmon from early (16 June - 8 July), middle (13 - 29 July), and late (5 August - 2 September) segments of the 1983 migration entering John Day Reservoir were collected at McNary Dam, wire-tagged, freeze branded, and released into the tailrace below the dam. Recoveries of these marks from the airlift fish collection facility at John Day Dam (Sims et al. 1981) were used to define reservoir travel and residence time.

Travel time for each release group was computed based on the first 25% of marked recoveries. This ensured that travel time and rate of movement data points calculated for each release group were based on actively migrating fish and adjusted for the possibility that later release groups may contain larger percentages of nonsmolting fish than earlier releases.

Average instream flows affecting each release group were calculated by averaging the daily river discharge at McNary Dam for the 10-day period following each release. Regression analysis was used to define the significance of travel time/f low relationships.

Residence time was calculated from the median date of the mark recoveries from each group. The use of median recovery dates ensures that the slower nonsmolting fish are included in the computation. The residence times calculated must be considered to be minimum since they were based only on recoveries at John Day Dam through 16 December. Surviving fish still in the reservoir were not included. Subsequent recaptures, if any, at John Day Dam in the spring and summer of 1984 would increase the average residence time calculations.

An 11-m power block purse seiner (NMFS research vessel Columbia) was used to sample 0-age chinook salmon in John Day Reservoir from 29 June to 29 September 1983. Sampling extended from the John Day Dam forebay [River Kilometer (RKm) 348] to just above Crow Butte, (RKm 430). Six sampling transects were established, with sets made near each shore and at mid-reservoir (Table 1). These transects were grouped into two major areas of the reservoir: lower (RKm 348-378) and middle (RKm 385-431).

Recoveries of marked fish by the purse seine from releases in the McNary Dam tailrace and from the Columbia were used to define 0-age chinook

^{b/} Difference between median date of recovery and release date.

salmon distribution and migratinalbehavior in John Day Rese rvoi r.

Purse seine catches were processed aboard the Columbia. Catches at John Day Dam were processed on site. All fish were anesthetized with W-222, counted, and examined for marks. Those fish to be marked were freeze branded. A subsample was measured for fork-length. After processing, all fish were allowed to recover from the anesthetic and released on site.

RESULTS AND DISCUSSION

A total of 94,765 0-age chinook salmon were marked and released into John Day Reservoir in 1983. Fifteen groups (72,559 fish) were wire-tagged, branded, and released into the tailrace at McNary Dam (Table 2). Of the fifteen groups released, four groups (20,033) were released during the early migration (29 June - 8 July), six groups (30,645) during the middle migration (13 - 29 July), and five groups (21,881) during the late migration (5 August - 2 September). An additional 22,206 fish from purse seine catches were marked and released at the six reservoir sampling transects (Table 3).

Total passage of 0-age chinook salmon at John Day Dam was estimated at 7.5 million fish. The airlift collection facility at John Day Dam captured 82,698 0-age chinook salmon between 27 May and 16 December 1983 (Table 4). Airlift catches included 640 marked fish from the McNary tailrace releases and 411 marked fish from purse seine releases. Detailed mark recovery information is included in Appendix Table X-1.

Purse seine sampling began on 29 June and was maintained on a 3-day/week schedule, when possible, through 29 September. One hundred

thirty-five (135) purse seine sets were made, and 22,484 0-age chinook salmon were captured (Tables 5 and 6). Purse seine catches included 345 marks from the McNary Dam tailrace releases and 113 marks from purse seine releases. Detailed purse seine mark recovery information is included in Appendix Table A-2.

Mean fork lengths of 0-age chinook salmon captured at McNary and John Day Dams and at purse seine sites throughout John Day Reservoir are shown in Table 7. Mean fork length increased from 103 mm (mid-June) to 166 mm (mid-December). Gross observations of subyearling migrants as they were examined for marks at both John Day Dam and in reservoir purse seine catches showed the fish to be in excellent condition. Preliminary analysis of stomach samples taken at the purse seine sites in 1982 and 1983 demonstrated a low number of empty stomachs and a high percentage of stomachs that were \geq half full. These data and the growth rate indicated by the weekly mean fork lengths indicated that the fish were actively feeding in the reservoir.

Incidental purse seine catches of species other than juvenile salmonids in John Day Reservoir are summarized in Table 8. Juvenile shad were again the most abundant species taken, only small numbers of other species were caught. Numbers and distribution of squawfish were similar to the 1982 catch.

Migrational Behavior

The 1983 migration of 0-age chinook salmon began to enter John Day Reservoir in early May and peaked at John Day Dam in mid-July. Fish were still being taken at John Day Dam on 16 December when monitoring was discontinued. The average reservoir residence time, based on median date

of mark recaptures, of branded 0-age chinook salmon released into the McNary Dam tailrace in 1983, was 21 days (range 3-155+) (Table 9). As in 1981 and 1982, the average reservoir residence time in 1983 suggests that a large percentage of the 0-age chinook salmon entering John Day Reservoir are not actively smolting.

Purse seine recoveries of marked subyearling chinook salmon released at various locations within the reservoir (excluding the McNary Dam tailrace releases) also indicate, as in 1981 and 1982, that a significant number of the fish are in a nonsmolting condition. Nearly 60% of the recoveries (66 of 111) were either at the same site (19) or upstream (47) from the original release site (Table 10). Such behavior is not representative of actively smolting fish.

Flow/Travel Time Relationships

Travel time (based on 25th percentile of mark recaptures) from McNary Dam to John Day Dam was calculated for the 15 groups of marked fish released into the McNary Dam tailrace in 1983 (Table 11). Average river flow for the 10-day period following each release ranged from 120 to 243 thousand feet³/second (kcfs). The average travel time ranged from 7 to 20 days. Considerable variance in travel time occurred regardless of river flow. Overall, average travel time for the early (13 d), middle (14 d), and Late (11 d) groups were nearly the same, although river flows declined from an average of 212 kcfs for the early group to 146 kcfs for the late group.

A regression line was constructed by plotting the travel time in hours for each release group against the appropriate river flow for the 15 groups

Table 9.--Average residence time (based on median date of recapture) of marked year Ling and subyearling chinook salmon in John Day Reservoir based on median date of recovery at John Day Dam, 1981, 1982, and 1983. Range appears in parentheses.

Marked fish	Residence time in days		
	1981	1982	1983

a/ For the 10-day period following each release date. Daily average river discharges at McNary Dam from 1 June to 30 September 1983 are given in Appendix A.

b/ 25th percentile.

in 1983 (Figure 1). The regression coefficient b (slope) of the line $y = 95.8 + 0.53x$ was examined for significance by testing the null hypothesis that the population regression coefficient is equal to zero ($H_0: b=0$). This was done by applying a sample t-test according to the formula: $t = \frac{b-B}{S_b}$ where b = slope and S_b = standard error of the regression coefficient.

where B = true population regression coefficient. The 15 data points developed showed a t value of 1.02. For a two-sided test of significance with 13 degrees of freedom with $\alpha = 0.05$, the table of t gave a value of ± 1.771 . Therefore, $H_0: b=0$ was accepted. Thus the slope (b) of this line did not possess a significant statistical difference from zero, and we found, as we did in 1981 and 1982, that there was no statistical evidence to indicate that river flows affected the rates of migration of 0-age chinook salmon migrating through John Day Reservoir (Miller and Sims 1983).

Flow/Survival Relationships

Samples of the three segments of the 0-age chinook salmon migration (early, middle, and late) entering John Day Reservoir in 1983 were wire-tagged and released into the McNary Dam tailrace. Adult returns from these releases will be used to determine relative survival of each segment. By plotting the survival estimates against the appropriate river flows, a regression line will be developed to determine if a significant flow/survival relationship existed.

SUMMARY AND CONCLUSIONS

1. Fifteen groups of 0-age chinook salmon (72,559 fish) were wire-tagged and branded at McNary Dam and released into the McNary Dam

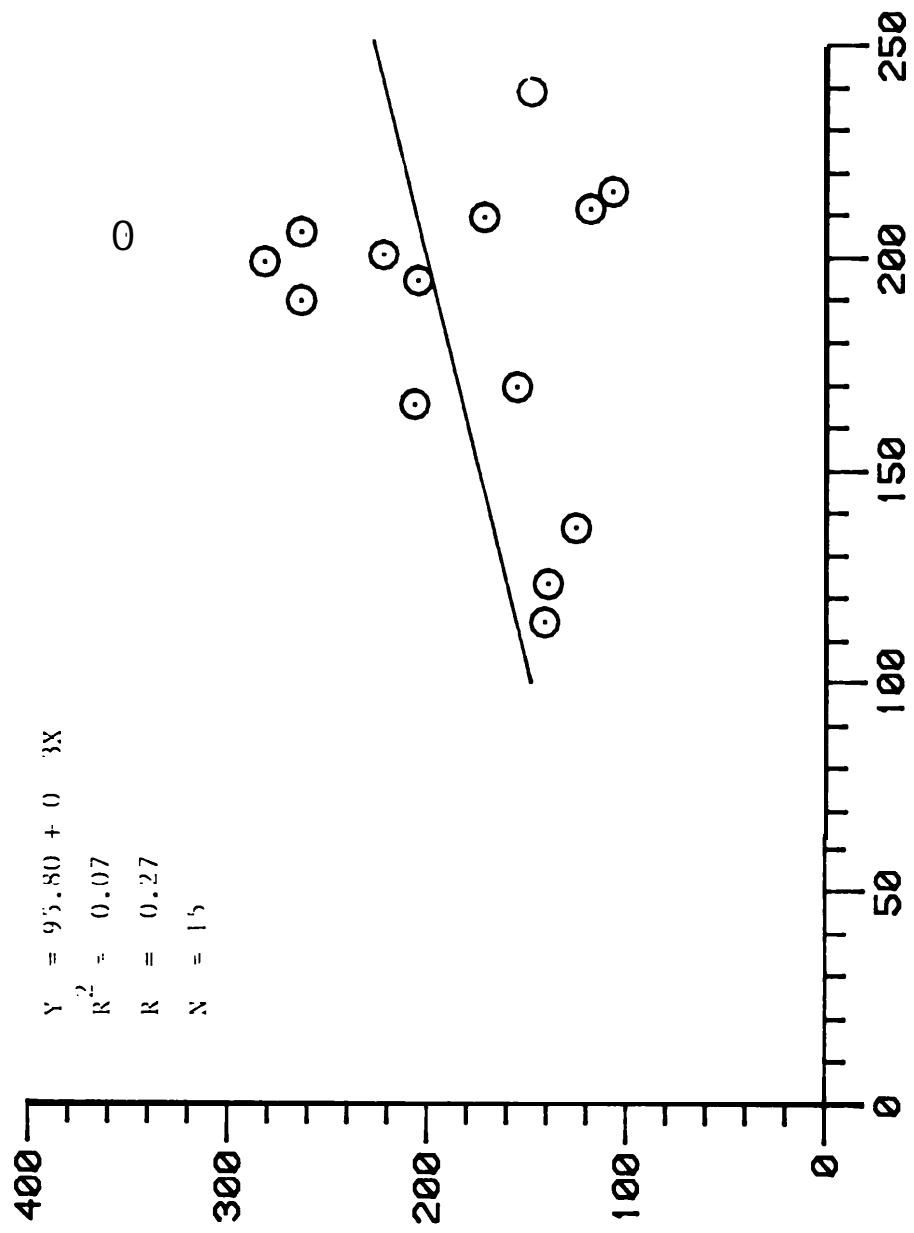

Figure 1.--Relationship of river flow to travel time of 0-age chinook salmon through John Day Reservoir (McNary Dam tailrace to John Day Dam), 1983.

tailrace during the period 16 June - 2 September 1983.

2. Additional mark releases of 22,206 purse seine captured 0-age chinook salmon were made at the six reservoir sampling transects.

3. The airlift collection facility in Turbine Unit 3, John Day Dam captured 82,698 0-age chinook salmon between 27 May and 16 December 1983. Total passage during this period, based on these collections, was estimated to be approximately 7.5 million fish.

4. Six hundred and forty marked 0-age chinook salmon were recovered at John Day Dam.

5. Between 29 June and 29 September, 135 purse seine sets were made in John Day Reservoir. Purse seine catches totaled 22,484 0-age chinook salmon with 458 mark recoveries.

6. Mean fork lengths of 0-age chinook salmon captured at McNary and John Day Dams and in the John Day Reservoir increased from 103 mm in mid-June to 166 mm in mid-December.

7. Gross examination of the subyearling migrants at John Day Dam and purse seine catches in the reservoir showed the fish to be in excellent condition. Preliminary analysis of stomach samples taken in 1982 and 1983 from purse seine catches demonstrated low numbers of empty stomachs and a high percentage of stomachs that were > half full. This would tend to substantiate the hypothesis that large numbers of 0-age chinook salmon are rearing in John Day Reservoir and may not be actively smolting.

8. The average residence time in John Day Reservoir for marked 0-age chinook salmon released into the McNary Dam tailrace was 21 days.

9. Sixty percent of purse seine mark recaptures of 0-age chinook salmon were made at or above the original release sites.

10. Length of residence and the amount of upstream movement suggests large numbers of subyearling migrants in John Day Reservoir may not be actively migrating.

11. Regression analysis based on 15 data points developed in 1983 provides no statistically significant evidence to indicate that river flows are affecting the rates of downstream movement or residence times of 0-age chinook salmon in John Day Reservoir.

ACKNOWLEDGEMENTS

Support for this research came from the regions electrical ratepayers through Bonneville Power Administration.
